Microwave QAM signals are traditionally generated by linearly mixing or modulating a VHF or UHF carrier oscillator with band limited I and Q information. The resulting phase and/or amplitude states of the carrier are then multiplied or upconverted by another mixer, local oscillator and sideband filter to the actual transmitted frequency. I/Q modulation has traditionally been done in this manner because lower frequency high isolation mixers tend to yield the best carrier and sideband rejection. The latter qualities are most important for accurate I/Q phase states or transmitted signal constellations. More recently at MITEQ, the electrical and physical symmetry of microwave baluns have been improved to yield mixers with LO-to-RF isolations of 45 dB up to 18 GHz. This unit uses these mixers to achieve direct I/Q modulation of a microwave carrier without the costly lower frequency upconversion.
